Abstract

The aim of this study is to produce monoacylglycerols (MAG) rich in polyunsaturated fatty acids (PUFA), especially eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), by glycerolysis of tuna oil with Lipase AK from *Pseudomonas fluorescence* immobilized on Accurel EP-100 (IM-AK). *tert*-Butyl methyl ether (MTBE) was the most suitable organic solvent after screening a list of different solvents and their mixtures. The optimum condition for MAG production was found to be 10 %w/v of tuna oil in MTBE, the mole ratio of glycerol to tuna oil 3:1, water added 4 wt% in glycerol, and the amount of IM-AK 30 wt% based on tuna oil. The temperature was controlled at 45°C. Under these conditions with 24 h reaction, the yield of MAG was 24.6% but containing 56.0 wt% PUFA (EPA and DHA). Stability of the IM-AK was also studied. The hydrolytic activity of the enzyme remained 88 and 80% of initial activity after incubated in MTBE for 24 h at 4 and 45 °C, respectively. The K_m and V_{max} values of the lipase-catalyzed glycerolysis of tuna oil in MTBE were found to be 19.47mM and 2.71mgMAG/min, respectively, for IM-AK.

Key words: Monoacylglycerols, glycerolysis, polyunsaturated fatty acids (PUFA), Immobilized lipase, Lipase AK, tuna oil

1 **Introduction**

2 Tuna oil is currently one of the major sources of polyunsaturated fatty acids
3 (PUFA), especially, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA).
4 The oil contains approximately 5.7% EPA and 18.8% DHA which are distributed in
5 mixed triacylglycerols (TAG) with ordinary fatty acids (Wongsakul, Prasertsan,
6 Bornscheuer and H-Kittikun, 2003). PUFA have received much attention in recent
7 years because of the health benefits including reduced risk of coronary disease,
8 prevention of certain cancers, and improved immune functions (Narayan, Miyashita
9 and Hosakawa, 2006; Ruxton, Reed, Simpson and Millington, 2004).

10 Monoacylglycerols (MAG) or mixtures with diacylglycerols (DAG) account
11 for approximately 75% of the emulsifier production and have various applications in
12 different fields (Bornscheuer, 1995; Damstrup, Jensen, Sparsø, Kiil, Jensen and Xu,
13 2005). MAG are nonionic emulsifiers widely used in bakery products, margarine,
14 dairy products, confectionary because of their emulsifying, stabilizing and
15 conditioning properties. Moreover, MAG are also used in pharmaceutical as binders
16 in tablets and as emollients for transdermal, slow-release drugs. Due to the worldwide
17 importance of MAG and their derivatives as surface active additives in a wide range
18 of foods, considerable attention has recently been paid to improve the synthesis of
19 MAG. They are also of great interest in synthetic organic chemistry where they are
20 utilized as synthetic intermediates and as chiral building blocks (Monteiro,
21 Nascimento and Ninow, 2003).

22 Chemically, MAG can be synthesized at high temperatures using several
23 metallic catalysts. Commercial MAG are widely manufactured by glycerolysis of fats
24 and oils. The glycerolysis reaction is accelerated by the use of inorganic alkaline
25 catalysis, such as NaOH or $\text{Ca}(\text{OH})_2$ at 220-260°C. However, this leads to a number

1 of unwanted side products and the reaction occurs in a random manner so that
2 extensive purification of products is required (McNeill & Yamane, 1991; Yang,
3 Rebsdorf, Engelrud and Xu, 2005; Damstrup et al., 2005). Furthermore, the high-
4 temperature chemical process is not suitable for the production of heat-sensitive MAG
5 containing PUFA, in particular from fish oils. Production of heat-sensitive MAG is,
6 however, of great commercial interest owing to their nutritive value, which could be
7 applied in foods and pharmaceuticals (Damstrup et al., 2005; Kaewthong & H-
8 Kittikun, 2005; Yang et al., 2005).

9 Due to disadvantages of the conventional process, the use of enzymes as
10 catalysts, thus, seems to be a potential as well as imperative alternative for practical
11 considerations. The much lower temperature used (less than 80°C) improves product
12 quality and makes production of heat-sensitive MAG feasible. Lipases have shown a
13 good stability and activity in hydrophobic solvents for MAG synthesis by glycerolysis
14 (Damstrup et al., 2005; Kristensen, Xu and Mu, 2005).

15 Several studies have dealt with the synthesis of MAG enriched in PUFA such as
16 alcoholysis of triacylglycerols with ethanol using a 1,3-regiospecific lipase or
17 glycerolysis of fish oil using an immobilized lipase (Sakiyama, Toshimi, Tanaka,
18 Osaki and Nakanishi, 2001; Wongsakul et al., 2003; Yang et al., 2005).

19 Glycerolysis of triacylglycerols (TAG) with lipase in the liquid phase typically
20 yields only 30-50% MAG (Bornscheuer, 1995; Kaewthong & H-Kittikun, 2005).
21 Some authors improved their systems by carrying out the reaction first in a liquid
22 state, but reducing the temperature to crystallize the formed MAG. This led to a shift
23 in the reaction equilibrium so that yields increased to 70-90%. However, continuous
24 production of MAG by this method was impossible (Kaewthong & H-kittikun, 2005).
25 For the bioconversion of various lipophilic or water-insoluble compounds, it is

essential to introduce organic solvents into reaction systems to improve the solubility of these reactants. Furthermore, use of suitable solvents system will result in more homogeneous system and enhance the conversion of substrate, the reaction rate, and the production distribution in favor of MAG formation as well as PUFA content in MAG.

In this work, under the decision of enzymatic glycerolysis with tuna oil as substrate, a list of solvents were first evaluated for the synthesis of MAG. Optimal reaction parameters were investigated in order to obtain MAG in high yields as well as with high PUFA (defined as EPA and DHA) content. Major focus was given to the enrichment of EPA and DHA in the MAG fraction.

Materials and methods

Materials

Crude tuna oil, with water content of 4.7%, was provided from Chotiwat Industrial Co. Ltd (Hat Yai, Thailand). The crude oil was obtained from skipjack tuna heads by a conventional pressing method. The refined oil was achieved through degumming, neutralization, bleaching, and deodorizing. Lipase AK, from *Pseudomonas fluorescens*, with water content of 0.04%, was a gift from Amano (Nagoya, Japan). Microporous polypropylene powder, Accurel EP-100 (particle size < 400µm) was a gift from Akzo Nobel (Obermburg, Germany). All other chemicals and solvents used were of reagent grade or analytical grade.

Hydrolytic activity of lipases

Hydrolytic activity of the immobilized lipase was determined by the modified cupric acetate method of Lee and Rhee (1993). One unit of hydrolytic activity was defined as

1 the amount of enzyme which liberates 1 μ mol equivalent of palmitic acid from palm
2 olein in 1 min at 30°C.

3 *Preparation of immobilized lipase*

4 Accurel EP-100 (10 g) was added to 100 ml of 0.1 M phosphate buffer (pH 7)
5 containing app. 100 U/ml Lipase AK and the reaction mixture was stirred with a
6 magnetic bar at 100 rpm for 30 min. Afterward, 100 ml of 0.1 M phosphate buffer
7 (pH 7) was added and the suspension was filtered through a Buchner funnel by
8 vacuum. The immobilized enzyme was washed with 100 ml of the buffer to remove
9 soluble enzyme and dried in a vacuum desiccator. The immobilized Lipase AK on
10 Accurel EP-100 (IM-AK) was stored at 4°C for further uses.

11 *Glycerolysis reaction*

12 The initial glycerolysis experiments were carried out in a batch system. The reaction
13 mixture consisted of IM-AK (water content 3.0%) 0.6 g, glycerol (99.5%, water
14 content 0.2%) 1.78 g, and 20 ml of 30% (w/v) of tuna oil in organic solvents. Extra 4
15 wt% water based on the glycerol was added directly to glycerol. The temperature was
16 controlled at 45°C. The reaction was mixed on the shaker at 300 rpm. Samples of the
17 reaction mixture were centrifuged to remove IM-AK before analysis.

18 *Analysis of glycerides by TLC-FID*

19 The components of oil phase were analyzed with a thin-layer chromatography and
20 flame ionization detector (TLC/FID) (IATROSCAN MK5, Iatron Laboratories Inc.
21 (Tokyo, Japan) for the content of TAG, 1,2(2,3)-DAG, 1,3-DAG, MAG and free fatty
22 acids (FFA) (Kaewthong & H-kittikun, 2005). The sample diluted in
23 chloroform/methanol (2:1 v/v) was spotted onto the chromarod and developed for 35
24 min in a mixture of benzene/chloroform/acetic acid (50:20:0.7 v/v/v) as developing
25 solvent. After development and drying, the rods were subjected to scanning with FID.

1 Standards were used to identify the peaks. The peak areas were normalized and used
2 for evaluation of the reactions.

3 *Analysis of fatty acids compositions*

4 The fatty acid compositions of glyceride species were determined by converting into
5 fatty acid methyl esters (FAME) followed by GC analysis. After evaporating
6 excessive solvent of the sample, the mixture was applied to the normal TLC-plate
7 with silica gel and developed in benzene/chloroform/acetic acid (50:20:0.7 v/v/v).
8 After drying, the MAG band was scraped off and methylated with 0.5%NaOH in
9 methanol (1000 µl) for 10 min at 60°C. The methyl esters were extracted with *n*-
10 hexane (300 µl) for 1 min. The *n*-hexane layer was washed with 200 µl distilled water
11 and dried over anhydrous sodium sulfate. Analysis was carried out with a Perkin-
12 Elmer Autosystem XL-GC gas chromatograph (Perkin-Elmer, Norwalk, CT) on a
13 FFFAP column (PERMABOND-FFFAP DF-0.25, 25m × 0.25mm *i.d.*, MACHEREY-
14 NAGEL, Germany). The carrier gas used was helium at a flow rate of 0.5 ml/min (15
15 *psi*) and operated in a split mode with a split ratio of 50:1. The temperature was started
16 from 150°C for 0.50 min and increased at the rate of 4°C/min to 170 °C, followed
17 with the rate of 5°C/min to 195°C, and further with the rate of 10°C/min to 215°C. the
18 temperature was kept at 215°C for 14 min. Injector and detector temperatures were
19 250°C (Joseph & Ackman, 1992). Response factors were determined using a standard
20 mixture of fatty acid methyl esters.

21 *Regiospecific analysis*

22 The regiospecific analysis of tuna oil was conducted by *Grignard* degradation with
23 allylmagnesium bromide followed by isolation, methylation, and GC analysis
24 (Soumanou, Bornscheuer and Schmid, 1998; Wongsakul et al., 2003).

25 *Karl Fischer water content determination*

1 The water content in the tuna oil, the immobilized lipase, and glycerol as well as in
2 the solvents was determined by Karl Fischer method (720 KFS Titrino, Switzerland,
3 using HYDRANAL titrant and solvents) (Xu, Fomuso and Akoh, 2000).

4 *Statistical analysis*

5 The SPSS program was used for data analysis (SPSS, 1989-2001). Analysis of
6 variance and t-test were used to evaluate the significance and difference of data.
7 Values were considered significant at $P < 0.05$ level.

8

9 **Results and discussions**

10 *1. Screening of solvents for the enzymatic glycerolysis of tuna oil.*

11 To select the most suitable solvent for the glycerolysis reaction system, the
12 effect of organic solvents on the catalytic activity of the lipase was examined. The
13 glycerolysis of tuna oil with IM-AK as biocatalyst was carried out in acetone, hexane,
14 isooctane, tert-butyl methyl ether (MTBE) and their combinations. The results are
15 shown in Fig. 1. It was found that MTBE gave the highest yield of MAG at 20.4 wt%
16 with yield of PUFA (EPA and DHA) about 14.8 wt%. Previously, Kaewthong and H-
17 Kittikun (2005) used the combination of acetone/isooctane mixture (3:1, v/v) as
18 solvent for glycerolysis of palm olein. Wongsakul et al. (2003) used acetone as
19 organic solvent for alcoholysis of tuna oil by Lipase PS-C. Moreover, Chang and
20 Rhee (1991) used isooctane as organic solvent for continuous glycerolysis of olive oil
21 in CSTR. Therefore, the selection of solvent seems affected by many different issues.
22 As information collected so far, it is strongly dependent on the selection of lipases.
23 Other issues such as oil type, reactor selection, and reaction mechanism might have
24 effect as well. As to this study, we decided to use MTBE for further study.

2. *Effect of water content*

Water content is recognized as an important factor in transesterification reactions. A certain amount of water is necessary to preserve the catalytically active conformation of the enzyme and to allow the formation of an acyl-enzyme complex. In contrast, excessive water causes acyl migration lead to decrease in MAG yield (Wongsakul et al., 2003). Therefore, optimal water content is the foremost important factor that should be sorted out in the quite hydrophilic solvent. Initial water content of the glycerol in the range of 4-12 wt% was studied. The results are shown in Fig 2. The highest yield of MAG of 20.7 wt% contained 15.7 wt% PUFA was obtained when 4% the water was added in glycerol. When more than 4 % water was added, the yield of MAG dropped gradually. This may be due to hydrolysis. Yamane, Kang, Kawahara and Koizumi (1994) found that FFA content at equilibrium depended on the water concentration in the glycerol phase. This can eventually lead to the decrease of MAG yields as early mentioned.

3. *Effect of substrate concentration in MTBE*

In a solvent system, the concentration of substrate will eventually affect the reaction rate based on Michaelis-Menten kinetics even though solvent can help create a homogeneous system. In order to select an efficient initial substrate (tuna oil) concentration for glycerolysis, the effect of tuna oil concentration was investigated. The results are shown in Fig. 3. The MAG yield increased with increasing the concentration of tuna oil as well as PUFA content in MAG increased when tuna oil concentration was increased. At the concentration of 10 % w/v tuna oil in MTBE with the mole ratio of glycerol to tuna oil about 3:1, the best yield of MAG at 22.1 wt% with PUFA content about 38.5 wt% was obtained after 24 h incubation. When the concentration of tuna oil was lower than 10 % w/v, the yield of MAG was decreased.

Solvent plays multiple roles and has more than one function in the system. It is first to make a homogeneous system and increase mass transfer by reducing the viscosity of the system. On the other hand, solvent may increase inhibition to the lipase since it deprives off water from the lipase structure. Certainly addition of solvent decreases the amount of available substrate at the interface between the solvent and glycerol and hence decreases the MAG yield. The amount of glycerol also plays a role in reactions and the system. Glycerol in the mixture would create difficulty for the reaction system if without solvent. On the other hand, Yang and Rhee (1991) suggested that glycerol could act as an effective stabilizer against thermal and solvent denaturation. However, Bornscheuer and Yamane (1994) showed that the optimum mole ratio of glycerol to palm olein for MAG production in the solid-phase system was 2.7:1 where at lower glycerol to TAG mole ratio (1:2), the main product of glycerolysis was diacylglycerols. Therefore, the amount of glycerol affected also the reaction equilibrium. In the present study, 10 % w/v of tuna oil with ca. 3 fold glycerol addition in moles gave the optimal system of the glycerolysis reaction.

4. Effect of IM-AK loading

The effect of IM-AK loading on MAG production was determined. The results are shown in Fig 4. When increasing the amount of IM-AK in the reaction mixture, the MAG production was also increased. However, no benefit came from increasing IM-AK above 30 wt% of tuna oil. Therefore, the amount of IM-AK 30 wt% of tuna oil was used for further study.

5. Effect of temperature

Temperature plays two roles in the reaction system. Firstly, higher temperature can reduce the viscosity as well as improve the substrate diffusion or its solubility. Secondly, enzymes usually have a temperature optimum. Therefore, an optimal

1 temperature should be selected in terms of the overall performance of the reaction.
2 The effect of temperature (30-50°C) on MAG production from tuna oil was studied.
3 When temperature was controlled in 30-45°C, the MAG production increased with
4 increasing temperature (data not shown). This result was a consequence of the
5 increase in the reaction rate. In contrast, when increasing the temperature from 45 to
6 55°C the yield of MAG was decreased. The temperature of 45°C was considered an
7 optimal temperature for the reaction system.

8 *6. Stability of IM-AK in MTBE mixture*

9 Stability of IM-AK in MTBE was studied at 4 and 45°C. The results show that
10 more than 88 and 80% of hydrolytic activity remained after incubation for 24 h,
11 respectively (data not shown). However, Fukui, Kawamoto, Sonomoto and Tanaka
12 (1990) found that benzene was better for lipase stability while gave a moderate result
13 for lipase activity. Kang and Rhee (1989) suggested that the immobilized lipase
14 activity in a reverse-phase system decreased as the polarity of solvent increases.
15 Kwon, Han and Rhee (1995) reported that the enzyme was stabilized by the substrate
16 in a two-phase reaction system (isooctane-water); the half-life of the enzyme was 10 h
17 without the substrate and 20 h with 30% olive oil at 30 °C. Stability is a very
18 complicated issue for many lipases. It not only relates to the characteristics of a lipase
19 but also relates to the reaction system selected. More work is needed to improve the
20 stability of the lipase used.

21 *7. MAG production under optimal conditions*

22 The optimal conditions for MAG production were decided as tuna oil
23 concentration of 10 %w/v in MTBE, the mole ratio of glycerol to tuna oil about 3:1,
24 water content in glycerol with 4 wt% and using IM-AK 30 wt% of tuna oil. The
25 temperature was controlled at 45°C. The reaction time course is given in Fig. 5. The

yield of MAG was 24.5 wt% and PUFA (EPA and DHA) content was 56.0 wt% after 24 h incubation.

The reaction products were separated by TLC. The fatty acid profiles of each band (glyceride species) were determined by GC (Table 1). As shown, monodocosahexylglycerol and monooleylglycerol were the predominant MAG in the products.

8. Kinetics of the glycerolysis using both Lipase AK and IM-AK

The kinetic constants (K_m and V_{max}) for glycerolysis of tuna oil with the non-immobilized Lipase AK as well as its immobilized form (IM-AK) were determined in MTBE by measuring initial reaction rates with varying amount of tuna oil (50-500mM). The results are shown in Fig 7. The values of the kinetic constants were obtained from Lineweaver-Burk plot. K_m and V_{max} of the original Lipase AK were 39.26 mM and 11.38 mgMAG/min, respectively; while K_m and V_{max} of IM-AK were 19.47 mM and 2.71 mgMAG/min, respectively. IM-AK had smaller K_m and V_{max} values than its original form, meaning the catalytic capacity of the immobilized form was reduced. The potential allowed substrate concentration is also reduced. A similar result was obtained in hydrolysis of olive oil by *Candida rugosa* lipase (Montero, Blanco, Virto, Landeta, Agud and Solozabal, 1993). In general, the immobilization of biocatalysts can lead to an activity reduction. It can also cause diffusional limitation of substrates in the immobilized biocatalyst system.

Conclusions

Glycerolysis of tuna oil was investigated to produce MAG rich in PUFA using immobilized Lipase AK. The optimum conditions for MAG production were found to be 10 %w/v of tuna oil in MTBE, glycerol to tuna oil ca. 3:1 mol/mol, water added in

1 glycerol was 4 wt% and the amount of IM-AK used was 30 wt% of tuna oil. The
2 temperature was controlled at 45°C. Under these conditions, the yield of 24.6 wt%
3 containing of 56.0 wt% PUFA (EPA and DHA) was obtained at 24 h. MAG were
4 produced in good yield with high content of PUFA, especially, EPA and DHA. Thus,
5 a suitable product or starting material for synthesis of structured triglycerides can be
6 obtained.

1 **Figure captions:**

2 Fig. 1. Screening of organic solvents on MAG production with IM-AK. The reaction
 3 mixture contained 20 ml of 30 %w/v tuna oil in organic solvents and 1.78 g
 4 glycerol with 4 wt% water. The amount of IM-AK used was 0.6 g (0.46
 5 U/mg). The reaction was carried out at 300 rpm and 45°C for 24 h. PUFA-
 6 polyunsaturated fatty acids, here meaning EPA and DHA and MAG-
 7 monoacylglycerol. The Y-axis indicates the MAG weight content in the
 8 normalized lipid species profile analyzed by TLA-FID and PUFA weight
 9 content in the normalized fatty acid composition of the MAG fraction
 10 analyzed by GC.

11 Fig. 2. Effect of water content in glycerol on MAG production by IM-AK. The
 12 reaction mixture contained 20 ml of 30 %w/v tuna oil in MTBE and 1.78 g
 13 glycerol with various amounts of water content. The amount of IM-AK used
 14 was 0.6 g (0.46 U/mg). The reaction was carried out at 300 rpm and 45°C for
 15 24 h. Abbreviations and notes to Y-axis see Figure 1.

16 Fig. 3. Effect of fish oil concentration on MAG production by IM-AK. The reaction
 17 mixture contained various amounts of tuna oil in 20 ml of MTBE and 1.78 g
 18 glycerol with 4 wt% water. The amount of IM-AK used was 0.6 g (0.46
 19 U/mg). The reaction was carried out at 300 rpm and 45°C for 24 h.
 20 Abbreviations and notes to Y-axis see Figure 1.

21 Fig. 4. Effect of IM-AK loading on MAG production. The reaction mixture contained
 22 20 ml of 10 %w/v tuna oil in MTBE and 1.78 g glycerol with 4 wt% water.
 23 The reaction was carried out at 300 rpm and 45°C for 24 h. Abbreviations and
 24 notes to Y-axis see Figure 1.

1 Fig. 5. Time course of glycerolysis by IM-AK in MTBE. The reaction mixture
2 contained 20 ml of 10 %w/v tuna oil in MTBE and 1.78 g glycerol with 4 wt%
3 water. The amount of IM-AK was used 0.6 g (0.46 U/mg). The reaction was
4 carried out at 300 rpm and 45°C for 24 h. Abbreviations see Figure 1.

5 Fig. 6. Lineweaver-Burk plots for Lipase AK and IM-AK-catalyzed glycerolysis of
6 tuna oil.
